Curve Fitting Overview

Chapter 1

This chapter provides an introduction to curve fitting. It includes information on the following topics:

- The purpose of performing curve fits.
- The types of curve fits that are available in KaleidaGraph.
- Choosing an appropriate curve fit model.

1.1 Purpose of Curve Fitting

Curve fitting, also known as regression analysis, is used to find the "best fit" line or curve for a series of data points. Most of the time, the curve fit will produce an equation that can be used to find points anywhere along the curve. In some cases, you may not be concerned about finding an equation. Instead, you may just want to use a curve fit to smooth the data and improve the appearance of your plot. KaleidaGraph provides curve fits that can be used in both of these scenarios.

1.2 Types of Curve Fits

The curve fits included in KaleidaGraph can be divided into three main categories: Least Squares curve fits, nonlinear curve fits, and smoothing curve fits. This section provides an overview of each category.

1.2.1 Least Squares Curve Fits

Least Squares is a method of curve fitting that has been popular for a long time. Least Squares minimizes the square of the error between the original data and the values predicted by the equation. While this technique may not be the most statistically robust method of fitting a function to a data set, it has the advantage of being relatively simple (in terms of required computing power) and of being well understood.

The major weakness of the Least Squared method is its sensitivity to outliers in the data. If a data point is widely different from the majority of the data, it can skew the results of the regression. For this reason, the data should always be examined for reasonableness before fitting. KaleidaGraph's Data Selection tool provides a simple method of graphically removing outliers from a plot.

The five Least Squares fits available in KaleidaGraph are: Linear, Polynomial, Exponential, Logarithmic, and Power. Section 2.1 contains a description of each fit and Section 2.2 provides an example of applying a Polynomial curve fit.

1.2.2 Nonlinear Curve Fits

Nonlinear curve fitting is accommodated in KaleidaGraph through the General curve fit function. Using this function, you can define your own equation or choose one from our library of over 100 curve fit definitions. This is the most powerful fitting option in KaleidaGraph because you can specify virtually any equation to be fitted to the data.

The General curve fit is based on the Levenberg-Marquardt algorithm and is calculated using an iterative procedure. KaleidaGraph starts with the initial guesses for the unknown parameters that were supplied with the equation. It then calculates a Chi Square value that represents the sum of the squared error between the original data and the calculated fit. During each iteration, KaleidaGraph varies the parameter values slightly and re-evaluates Chi Square until it finds the best fit.

Chapter 3 contains more information on the use of the General curve fit function.

1.2.3 Smoothing Curve Fits

The smoothing fits in KaleidaGraph are different from the other two types of fits in that these curve fits do not generate an equation for the resulting curve. This is because there is no single equation that can be used to represent the curve. These curve fits are useful when you just want to improve the appearance of the plot by drawing a smooth curve through the data.

The four smoothing fits available in KaleidaGraph are: Smooth, Weighted, Cubic Spline, and Interpolate. Each one of these curve fits uses a different technique to arrive at the final curve, so you may want to apply more than one to see which one looks the best.

The Smooth and Interpolate curve fits are based on the same underlying technique, with the Smooth curve fit incorporating a geometric weight to arrive at the final curve. The Weighted curve fit uses the locally weighted Least Squares error (Lowess) method. The Cubic Spline curve fit is calculated using a series of cubic polynomials. Section 4.1 contains a description of each fit and Section 4.2 provides an example of applying a Cubic Spline curve fit.

1.3 Choosing a Curve Fit Model

Since KaleidaGraph provides a number of different curve fit types and over 100 General curve fit equations, choosing a model for a particular data set can be a difficult task. When you are deciding on a curve fit model, it helps to know some of the underlying properties associated with the data to make an educated decision on which model to use.

Depending on your field of study, you may find that certain equations or families of equations are used on a regular basis. For example, Sigmoidal curves are normally used to fit dose response data and Hyperbolic functions are normally used to fit ligand binding data in the field of enzyme kinetics.

If you do not know what type of curve fit to use, you may be able to ask a colleague or do some research to see what curve fits are normally used with the type of data that you have collected. If that proves to be fruitless or if nothing is known about the data, then the selection of the model must be based on the raw data.

You can use a Scatter plot to plot the data and see the general shape of the curve. The following figures provide a glimpse of the general shape associated with some of the more common families of General curve fits that are used in KaleidaGraph. Within each family, KaleidaGraph provides a number of different curve fit equations and it may take some trial and error to find the equation that produces the best results.

General Shape of Various Curve Fit Families

Using Least Squares Curve Fits

Chapter 2

This chapter provides information on the five Least Squares curve fits available in KaleidaGraph and includes an example of applying a Polynomial curve fit to a plot.

2.1 KaleidaGraph's Least Squares Curve Fits

2.1.1 Linear

This function fits a straight line through your data, of the form y = m0 + m1 * x. There are no data restrictions associated with this curve fit.

Note: On a semi-log or log-log plot, this fit appears as a curved line.

2.1.2 Polynomial

This function fits a curve through your data, of the form $y=m0 + m1 * x + m2 * x^2 + m3 * x^3 +...+ m9 * x^9$. The more complex the curvature of the data, the higher the polynomial order required to fit it. There are no data restrictions associated with this curve fit.

2.1.3 Exponential

This function fits a curve through your data, of the form $y = m0 * e^{m1 * x}$. It is generally used to fit data that increases or decreases at a high rate. This curve fit cannot fit negative data or data equal to zero.

Note: On a semi-log plot with a linear X axis, the curve appears as a straight line.

2.1.4 Logarithmic

This function fits a curve through your data, of the form y = m0 + m1 * log(x). A logarithmic curve fit is generally used with data that spans decades (10^0, 10^1, 10^2, and so on). This curve fit cannot be used to fit negative data or data equal to zero.

Note: On a semi-log plot with a linear Y axis, the curve appears as a straight line.

2.1.5 Power

This function fits a curve through your data, of the form $y = m0 * x^{m1}$. This curve fit cannot be used to fit negative data or data equal to zero.

Note: On a log-log plot, the curve appears as a straight line.

2.2 Applying a Least Squares Fit

The following steps explain how to apply a Least Squares fit, using the Polynomial curve fit as an example. The procedure is basically the same for applying the other Least Square fits. Example 2 in the KaleidaGraph Quick Start Guide shows how to apply a Linear curve fit to a Scatter plot.

To apply a Polynomial curve fit:

1. Open the plot window which will have the curve fit applied. Figure 2-1 shows a sample plot.

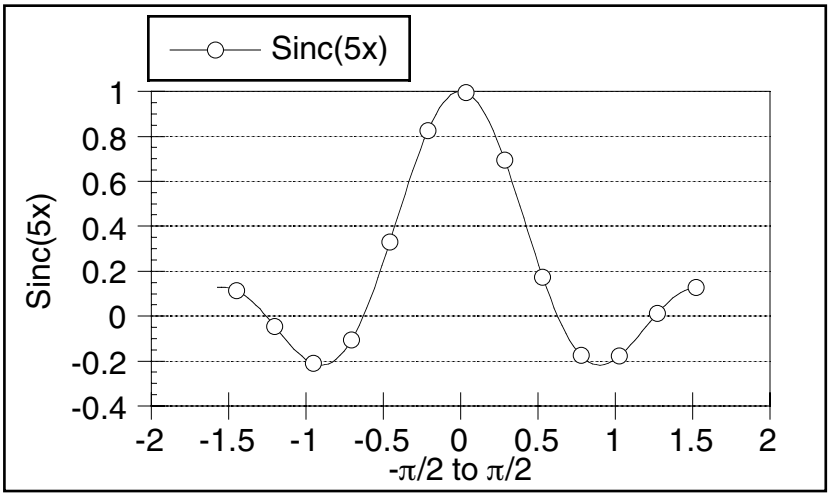

Figure 2-1 Sample plot

2. Choose **Curve Fit > Polynomial**. A Curve Fit Selections dialog similar to Figure 2-2 appears. All dependent variables are listed under **Column Names**.

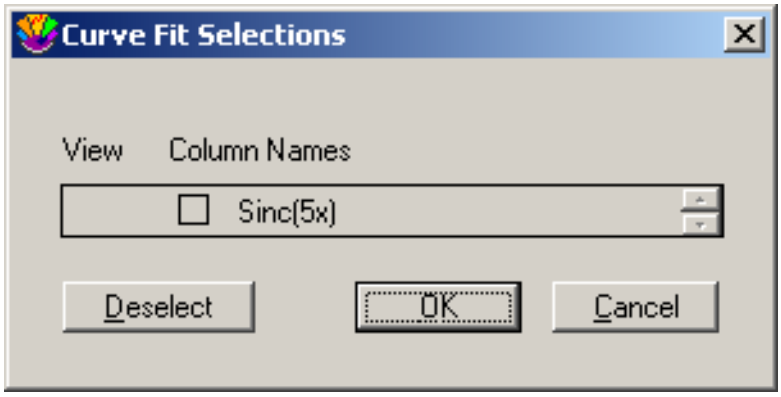

Figure 2-2 Curve Fit Selections dialog

3. Click the check box for each variable to be fit. A keyboard shortcut (**Ctrl+A** under Windows or ⌘**+A** on a Macintosh) is available to select all of the variables at once. Each time a variable is selected, a second dialog appears (Figure 2-3). Use this dialog to specify the order of the polynomial to be fit. The maximum value that can be selected is nine.

   Note: This extra dialog is only displayed when using the Polynomial fit.

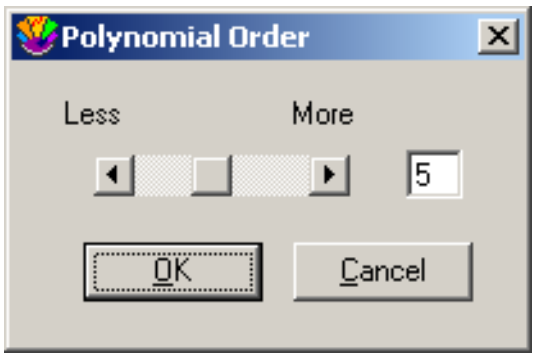

Figure 2-3 Polynomial Order dialog

4. Click **OK** to exit each dialog and apply the curve fit.

   After the curve fit is applied, you can display its equation or extrapolate the fit to the axis limits. These are a few of the features covered in Chapter 6 of this guide. Figure 2-4 shows the sample plot after applying a Polynomial curve fit (represented by the dashed line) and displaying the equation.

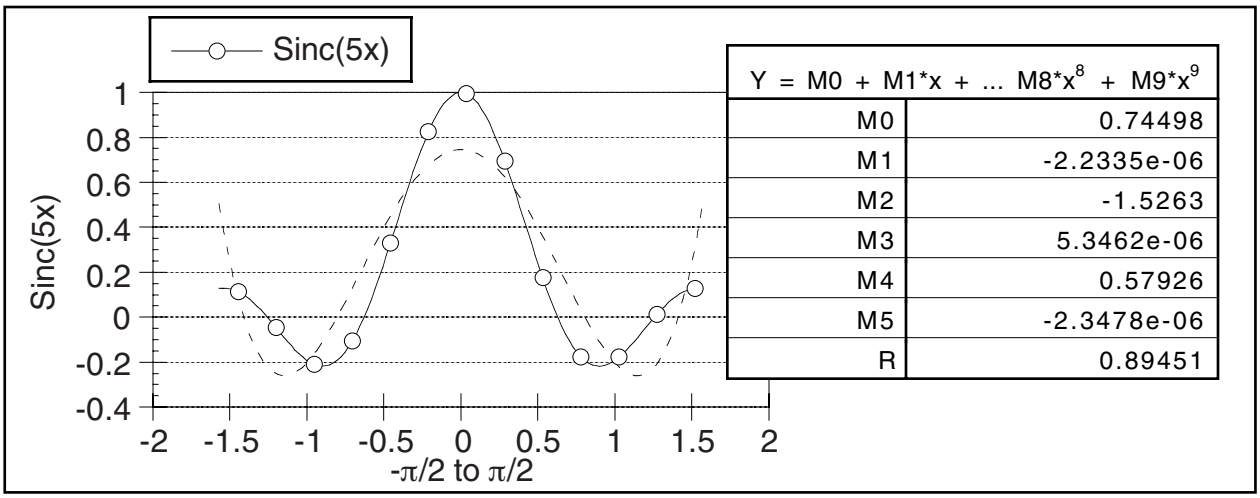

Figure 2-4 Sample plot with Polynomial curve fit applied

Using Nonlinear Curve Fits

Chapter 3

This chapter provides information on the nonlinear curve fit available in KaleidaGraph. It also covers some basic concepts, including:

- Structuring the curve fit definition and initial guesses.
- Managing the master curve fit list.
- Using the predefined curve fit equations.
- Entering a custom curve fit definition.
- Applying a General curve fit.
- Using weights when applying a General curve fit.

3.1 Introduction to the General Curve Fit

This is the most powerful curve fit in KaleidaGraph. It takes a user-defined equation and uses it to fit a set of plotted data. Any function of x or m0, where either x or m0 is the independent variable, can be defined using up to nine parameters (m1–m9).

Examples:

```
m1 * m0
m1 + m2 * m0
m1 * exp(–m2 * m0)
```

When a General curve fit is selected, a curve, defined by the equation in the Curve Fit Definition dialog, is fitted to the data using the Levenberg-Marquardt algorithm. There are no data restrictions associated with this curve fit.

3.2 General Curve Fit Basics

This section explains the structure of the curve fit equation, setting initial conditions for the parameters, the Curve Fit Definition dialog, and the use of the commands in the **General** submenu.

3.2.1 Curve Fit Definition

The curve fit definition is the equation that is fitted to the data. Curve fit definitions are composed of the same items as formulas in Formula Entry: operators, parameters, functions, and constants, in addition to an independent variable. When entering the curve fit definition, follow these guidelines:

- The independent variable in an equation is represented by m0.
- The parameters being calculated by the fit are represented by m1–m9. Parameters should be entered wherever you have an unknown quantity and you want KaleidaGraph to calculate the best value.
- Use an asterisk (*) for multiplication and a caret (^) for raising quantities to a power.
- KaleidaGraph does not distinguish between upper and lower case letters (m0 and M0 are the same).
- Constants and other shorthand references can be defined in the library for use in a curve fit definition. Some definitions in the default library are used to substitute x for m0, and a, b, c, and d for m1, m2, m3, and m4, respectively.
- To include a column number as part of the curve fit definition, the **table** function must be used. Section 3.3.5 shows how to use the table function in a General curve fit definition. This method also enables you to fit equations containing multiple independent variables.

The following table lists some equations and how they appear as curve fit definitions in KaleidaGraph.

Original Equations	Curve Fit Definitions
a * x + b	m1 * m0 + m2
a + b * x^c	m1 + m2 * m0^m3
a + b * exp(–c * x)	m1 + m2 * exp(–m3 * m0)
a * exp(–b * x) * cos(c * x + d)	m1 * exp(–m2 * m0) * cos(m3 * m0 + m4)

3.2.2 Initial Conditions

Even though KaleidaGraph calculates values for unknown parameters, you must supply an initial value for each parameter. The algorithm used to calculate the final results requires a reasonable guess to point it in the right direction. KaleidaGraph improves upon these values during each iteration of the fit.

Note: Since the fit starts with initial guesses and improves upon them with each iteration, the final values may be different for a separate set of initial guesses.

Do not get carried away trying to find good guesses; the initial conditions are just that, guesses. If you are not sure what the guesses should be, keep the initial conditions non-zero, and at the correct order of magnitude that you might expect (be it 0.001, 1, or 1000).

The initial conditions are entered immediately following the curve fit definition. Place a semicolon at the end of the definition and begin entering the initial guesses, separating each with a semicolon. The table below shows the definitions from the previous section with some sample initial guesses.

Curve Fit Definitions with Initial Guesses
m1 * m0 + m2; m1 = 0.5; m2 = 23
m1 + m2 * m0^m3; m1 = –2; m2 = 3; m3 = 2
m1 + m2 * exp(–m3 * m0); m1 = 5; m2 = 1; m3 = 0.5
m1 * exp(–m2 * m0) * cos(m3 * m0 + m4); m1 = 4; m2 = 0.7; m3 = 2.2; m4 = 15

3.2.3 Curve Fit Definition Dialog

The Curve Fit Definition dialog is used to enter the equation, initial guesses, and allowable error to be used in the curve fit. You can also choose to specify partial derivatives or to weight the data.

This dialog can be displayed using either of the following methods:

- Choose a curve fit from the **General** submenu (**Curve Fit** menu). In the dialog that is displayed, click **Define**.
- Choose **Curve Fit > Edit General**. In the dialog that is displayed, select the name of a curve fit and click **Edit**.

The various features of the Curve Fit Definition dialog are discussed below.

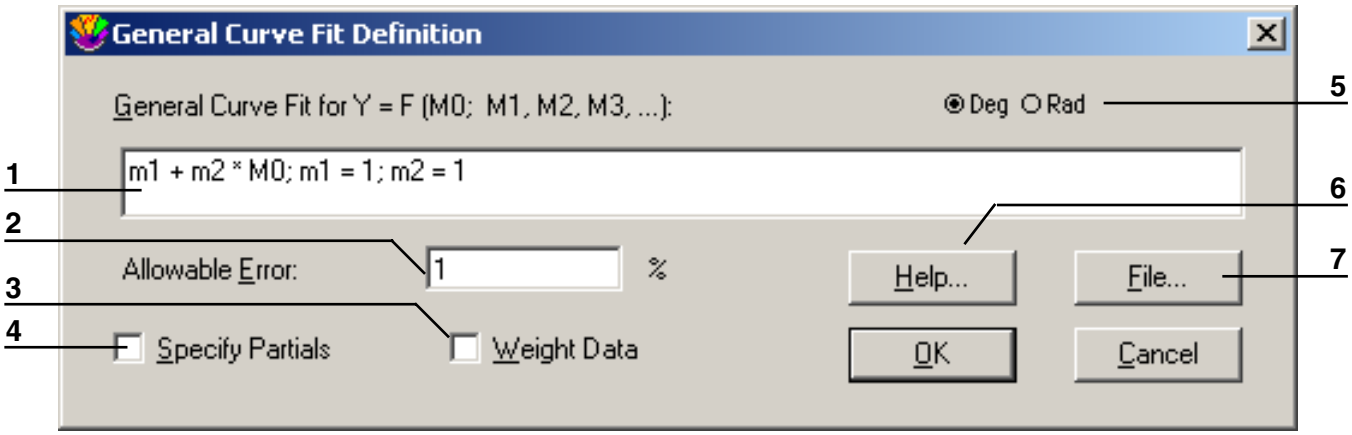

Figure 3-1 Curve Fit Definition dialog

1. **Text Field**
   Curve fit definitions and initial guesses are entered in this area of the dialog.

2. **Allowable Error:**
   The value entered in this field helps KaleidaGraph determine when to stop iterating. Iterations stop if either of the following occurs:

   - Chi Square does not change for a certain number of iterations.
   - The percent change in the normalized Chi Square is less than the Allowable Error.

3. **Weight Data**
   When selected, you can specify a data column that contains weights for the variable you are fitting. These weights should represent the individual errors of the data values. Each weight is used internally as:
   1/(weight^2). The smaller the error value, the larger the internal weight. If this check box is not selected, a weight value of 1.0 is used for all data points.

4. **Specify Partials**
   The algorithm that KaleidaGraph uses in calculating each iteration of the General curve fit requires evaluating the partial derivative of the function with respect to each parameter. If **Specify Partials** is not selected, KaleidaGraph numerically approximates the derivative. If this option is selected, the dialog expands, as shown in Figure 3-2.

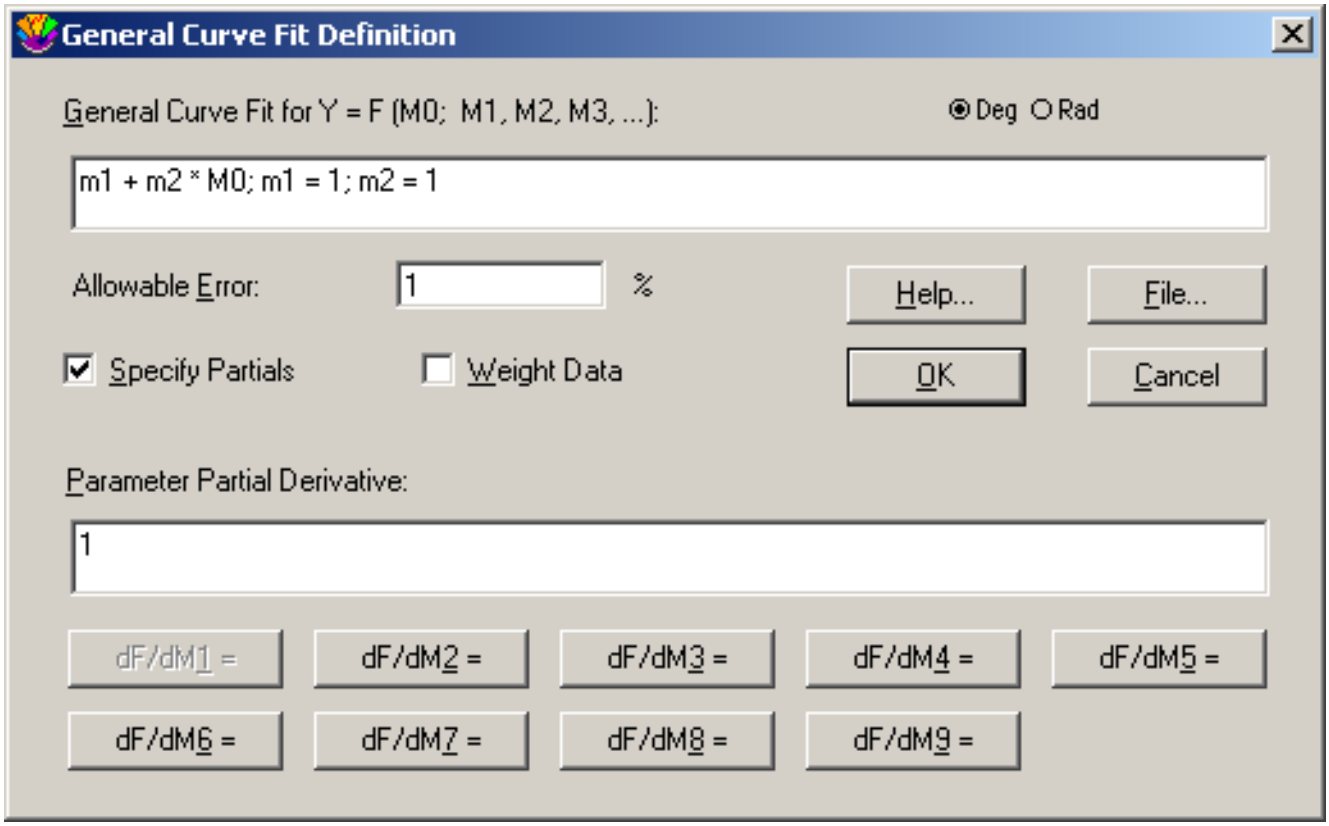

Figure 3-2 Expanded Curve Fit Definition dialog

The nine buttons at the bottom of the dialog allow each partial derivative to be entered in the text field above the buttons. The biggest advantage of specifying the partial derivatives is accuracy. The curve fit algorithm uses these partial derivatives to direct itself where to move after each iteration to find the best solution.

You can choose to specify only some of the partial derivatives, but not all of them. It is better to let KaleidaGraph approximate the partial instead of specifying the wrong derivative. If a partial derivative is missing, KaleidaGraph numerically approximates that partial derivative.

5. **Degrees/Radians Buttons**
These buttons determine whether the results of trigonometric functions are in degrees or radians.

6. **Help...**
Click this button to display the Help dialog.

7. **File...**
Clicking this button displays a text editor that can be used to create, open, or save a curve fit definition. The definition appears on the first line and any partial derivatives appear on the lines below it.

3.2.4 Managing the Curve Fit List

KaleidaGraph maintains a master list of curve fits in the **General** submenu. This submenu can store up to 16 user-defined equations that can be applied whenever a new plot is created.

The following sections explain how to edit and save changes to the curve fits listed in the General submenu.

Note: The only way to edit the master list is to create a new plot and use the **Edit General** command. The master list is not affected if you do either of the following:

- Use a saved plot (or any plot that had its data archived).
- Choose a curve fit from the **General** submenu and click **Define** to edit the definition.

Adding a Curve Fit to the Master List

To add a curve fit to the master curve fit list:

1. Create a new plot.
2. Choose **Curve Fit > General > Edit General**. The dialog in Figure 3-3 appears.

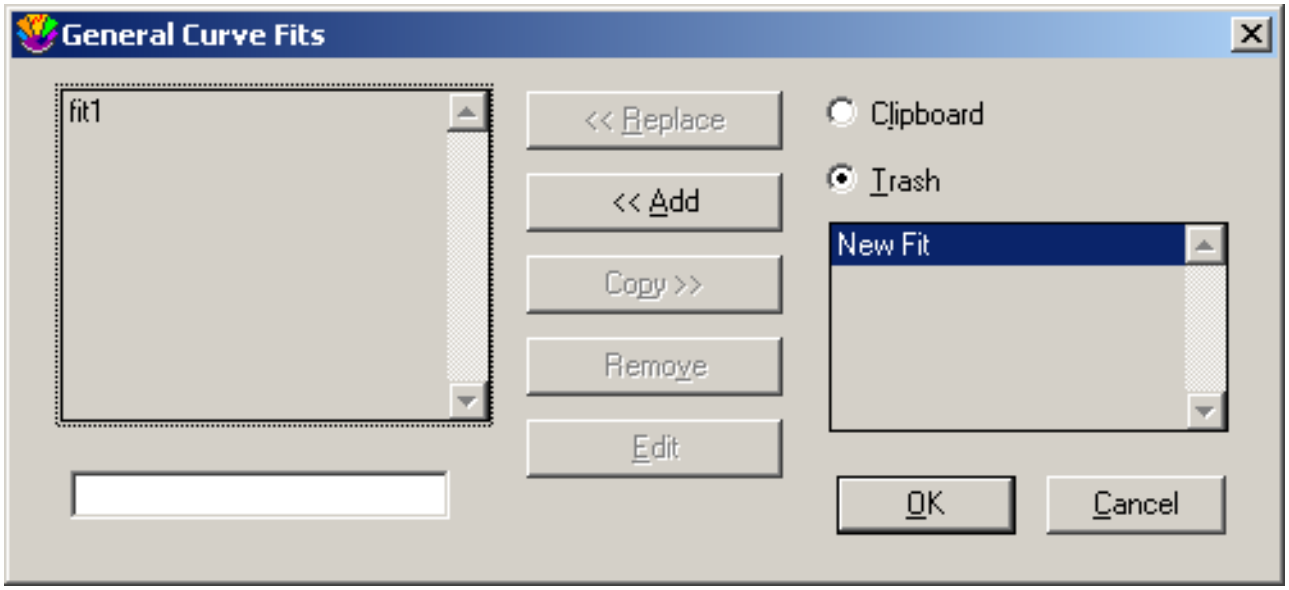

Figure 3-3 Edit General dialog

3. Select a fit in the current list.
4. Click **Add** and a **New Fit** appears below the selected fit in the list. The name of the fit can be changed by selecting it and editing the name in the text field.
5. Click **Edit** to enter the definition in the Curve Fit Definition dialog.
6. Click **OK** when you are finished. Now you can use this fit in the active plot or any new plots that are created. Remember to save changes to the Macros file to make the changes permanent.

Rearranging the Master Curve Fit List

To rearrange the curve fit list:

1. Create a new plot.
2. Choose **Curve Fit > General > Edit General**.
3. Select the curve fit to be repositioned.
4. Click **Copy** to copy the fit to the trash bin.
5. Click **Remove** to delete the name from the listing.
6. Select a curve fit in the current list.
7. Select the name of the curve fit that was copied to the trash bin.
8. Click **Add** and the curve fit appears below the selected fit in the list.

Note: When rearranging curve fits, do not leave the Edit General dialog until you are completely finished. As soon as you click **OK** or **Cancel** in this dialog, anything in the trash bin is deleted. The only permanent trash bin item is **New Fit**.

Removing a Curve Fit from the Master List

To remove a curve fit from the master list:

1. Create a new plot.
2. Choose **Curve Fit > General > Edit General**.
3. Select the curve fit to be deleted.
4. Click **Remove** to delete the curve fit from the listing.
5. Click **OK**.

Adding Curve Fits from the Master List to Saved Plots

When a saved plot is opened, the **General** submenu displays the curve fits that were available when the plot was originally created, regardless of what is currently in the master list. To add curve fits from the master curve fit list to a saved plot:

1. Open a saved plot.
2. Choose **Curve Fit > General > Edit General**. The curve fits stored in the master list appear below the dotted line in the trash bin.
3. Select the name of the curve fit to be added from the trash bin listing.
4. Select a fit in the current list.
5. Click **Add** and the curve fit appears below the selected fit in the list.
6. Click **OK** when you are finished. Now you can use this fit in the saved plot.

Saving Changes to the Curve Fit Menu

The curve fits in the **General** submenu are saved, by default, in a file called **KG Macros**. This file is loaded each time you start KaleidaGraph.

To save any changes made to the **Curve Fit** menu, it is necessary to save the changes to the default Macros file using one of the following methods:

- In the Preferences dialog, select **Prompt** from the **Macros** pop-up menu. When exiting KaleidaGraph, a dialog asks whether or not to overwrite the Macros file that was opened at launch.
- In the Preferences dialog, select **Always** from the **Macros** pop-up menu. When exiting KaleidaGraph, the Macros file that was opened at launch is automatically overwritten.
- Choose **File > Export > Macros** and overwrite the default Macros file.

Note: Only changes made to a new plot using the **Edit General** command are saved as part of the macros file. Any changes made to a saved plot or by choosing a curve fit from the **General** submenu and clicking **Define** apply solely to that particular plot.

3.3 Using the General Curve Fit

This section explains how to define and apply a General curve fit equation. Other topics include weighting data, limiting parameters, and defining equations in the library. If you are new to using the General curve fit, refer to Section 3.2 which covers some basic concepts, including equation structure, initial conditions, the Curve Fit Definition dialog, and managing the curve fit list in the **General** submenu.

3.3.1 Using the Predefined Curve Fit Definitions

KaleidaGraph includes over 100 curve fit definitions that are divided into several categories (Polynomial, Logarithmic, Sigmoidal, and so on). These curve fit definitions are provided in the following formats for use in KaleidaGraph:

- Each curve fit definition is stored as a text file in the **Curve Fits** folder.
- Each category of definitions is stored as a Macros file that can be imported to load the definitions into the **General** submenu.
- Each category of definitions is stored as a text file for use in the Library.

Importing Definitions from a Text File

The **Curve Fits** folder contains each curve fit definition as a text file. This allows you to import specific curve fit definitions for use in KaleidaGraph.

To load a text file containing a curve fit definition (and have it available for all future plots):

1. Create a new plot.
2. Choose **Curve Fit > General > Edit General**. The dialog in Figure 3-4 appears.

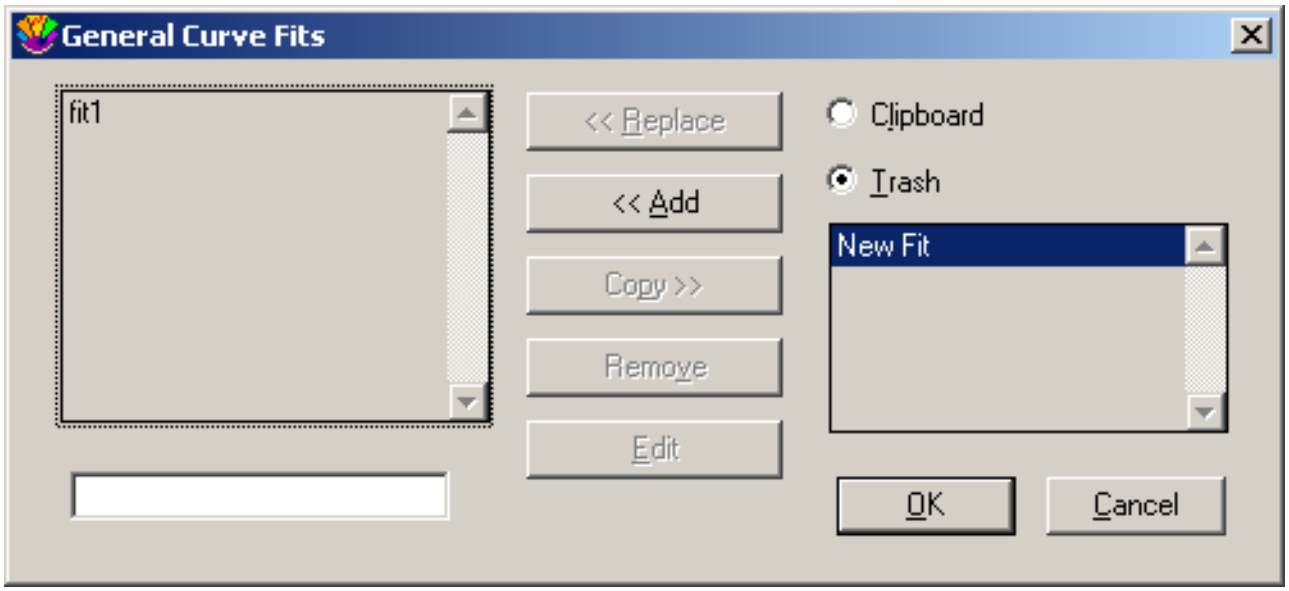

Figure 3-4 Edit General dialog

3. Select a fit in the current list.
4. Click **Add** and a **New Fit** appears below the selected fit in the list. The name of the fit can be changed by selecting it and editing the name in the text field.

5. Click **Edit** to display the Curve Fit Definition dialog.
6. Click **File** in the Curve Fit Definition dialog. A text editor appears.
7. Choose **File > Open**.
8. Locate and open a curve fit definition from the **Curve Fits** folder. The definition and initial guesses for the parameters will be displayed in the editor.
9. Choose **File > Close** to display the curve fit equation in the Curve Fit Definition dialog. Make sure you change the initial guesses, because all of the initial guesses are set equal to 1.0 by default.
10. Click **OK** until you return to the plot window. Now you can use this fit in the active plot or any new plots that are created. Remember to save changes to the Macros file to make the changes permanent.

Importing Definitions from a Macros File

The **Macros** folder contains a Macros file for each category of curve fit definitions. Importing one of these Macros files loads the curve fit definitions into the **General** submenu.

Note: If a plot is already open, you will not see the imported curve fit definitions until a new plot is created.

To load the definitions from a Macros file:

1. Choose **File > Open**.
2. Locate and open the Macros file of interest from the **Macros** folder.
3. Create a new plot. The curve fit definitions stored in the Macros file will be listed under the **General** submenu.
4. You can now apply one of these fits to your data. Make sure you change the initial guesses, because all of the initial guesses are set equal to 1.0 by default.

Importing Definitions into the Library

The **Library** folder contains text files for each category of curve fit definitions. These text files can be loaded into the library for use in the General curve fit.

To load a text file into the library:

1. Choose **Macros > Library** or **Curve Fit > General > Library**.
2. Choose **File > Open**.
3. Locate and open the curve fit category of interest from the Library folder.
4. Browse through the library and make note of the shorthand reference and number of unknowns for the curve fits that you will be using.
5. Choose **File > Close**.

You can now use these library definitions to apply a General curve fit. When entering the definition in the Curve Fit Definition dialog, you can enter the shorthand reference defined in the library with the initial guesses, for example **gaussfit(1,5,1,10)**. KaleidaGraph will perform the necessary substitutions before applying the fit.

3.3.2 Entering a Custom Curve Fit Definition

If you need to use a curve fit equation that is not included with the predefined equations, you can easily enter a custom equation and use it in KaleidaGraph.

Note: Custom curve fit equations can also be defined in the library. Refer to the KaleidaGraph manual or online help for more information.

To create a custom curve fit definition (and have it available for all future plots):

1. Create a new plot.
2. Choose **Curve Fit > General > Edit General**.
3. Select a fit in the current list.
4. Click **Add** and a **New Fit** appears below the selected fit in the list. The name of the fit can be changed by selecting it and editing the name in the text field.
5. Click **Edit** to display the Curve Fit Definition dialog.
6. Enter the curve fit equation in the Curve Fit Definition dialog. Make sure you include the initial guesses for each of the unknown parameters. Figure 3-5 shows an example curve fit equation and its initial guesses.

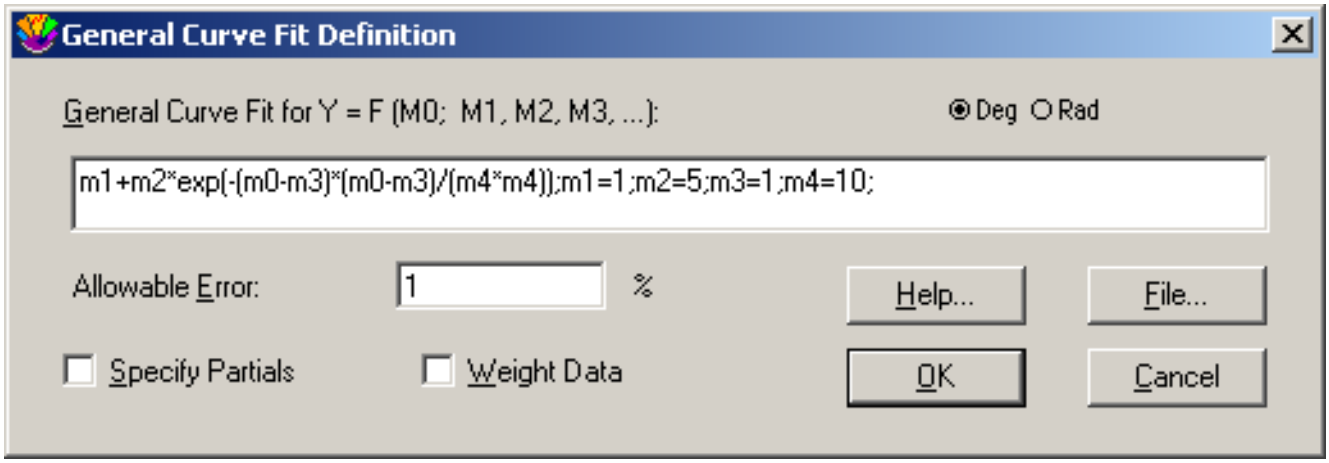

Figure 3-5 Example curve fit equation

7. Click **OK** until you return to the plot window. Now you can use this fit in the active plot or any new plots that are created. Remember to save changes to the Macros file to make the changes permanent.

3.3.3 Applying a General Curve Fit

To apply a General curve fit:

1. Open the plot window which will have the curve fit applied. Figure 3-6 shows a sample plot.

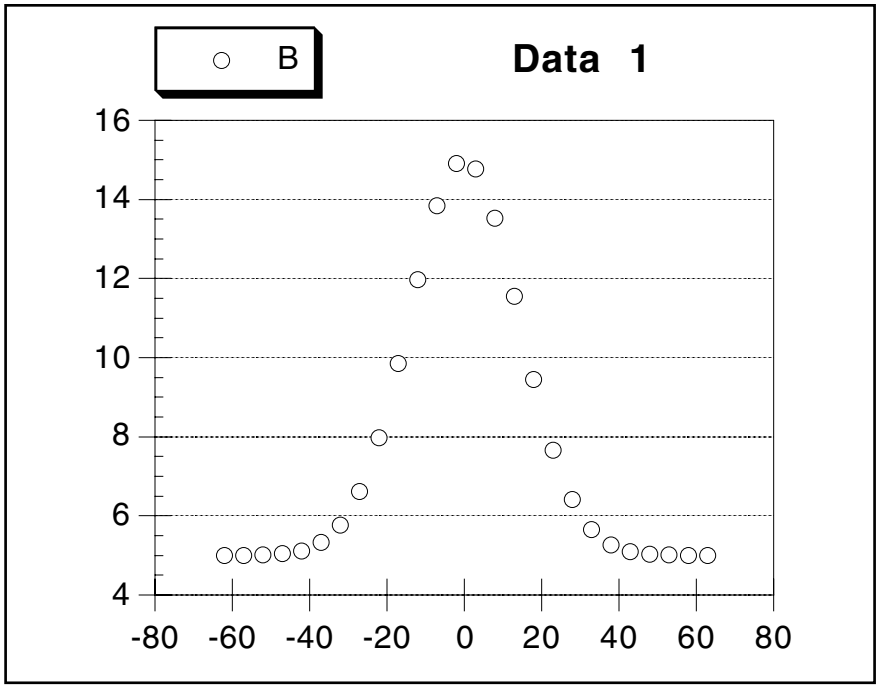

Figure 3-6 Sample plot

2. Choose a curve fit from the **General** submenu (**Curve Fit** menu). A Curve Fit Selections dialog similar to Figure 3-7 appears. All dependent variables are listed under **Column Names**.

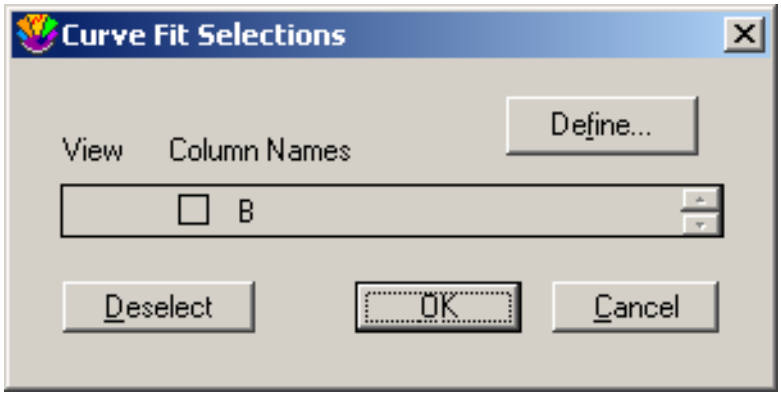

Figure 3-7 Curve Fit Selections dialog

3. If the equation has not been entered, click **Define** to enter the equation or shorthand reference to be applied to the data. Figure 3-8 shows the Curve Fit Definition dialog containing a curve fit definition. When you are finished, click **OK**.

   Note: For information on including this fit in your master curve fit list, refer to Section 3.2.4.

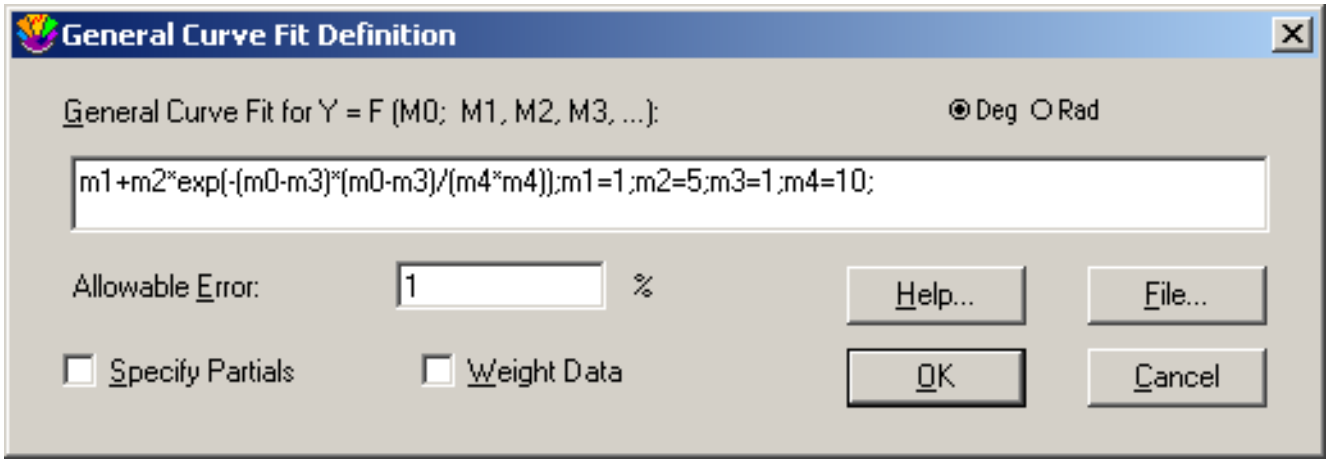

Figure 3-8 Curve Fit Definition dialog

4. Click the check box of each variable to be fit. Typing **Ctrl+A** (Windows) or ⌘+**A** (Macintosh) selects all of the variables at once.

5. Click **OK** to apply the curve fit. A status dialog will show the progress of the curve fit. It is updated after each iteration.

   Note: Typing **Ctrl+Period** (Windows) or ⌘+**Period** (Macintosh) cancels a General curve fit. The current state of the fit is calculated and the resulting curve is drawn.

   When the curve fitting process is complete, the curve is drawn on the plot. Once the curve fit is applied, you can display its equation or extrapolate the fit to the axis limits. These are a few of the features covered in Chapter 6 of this guide. Figure 3-9 shows the sample plot after applying a General curve fit (represented by the dashed line) and displaying the equation.

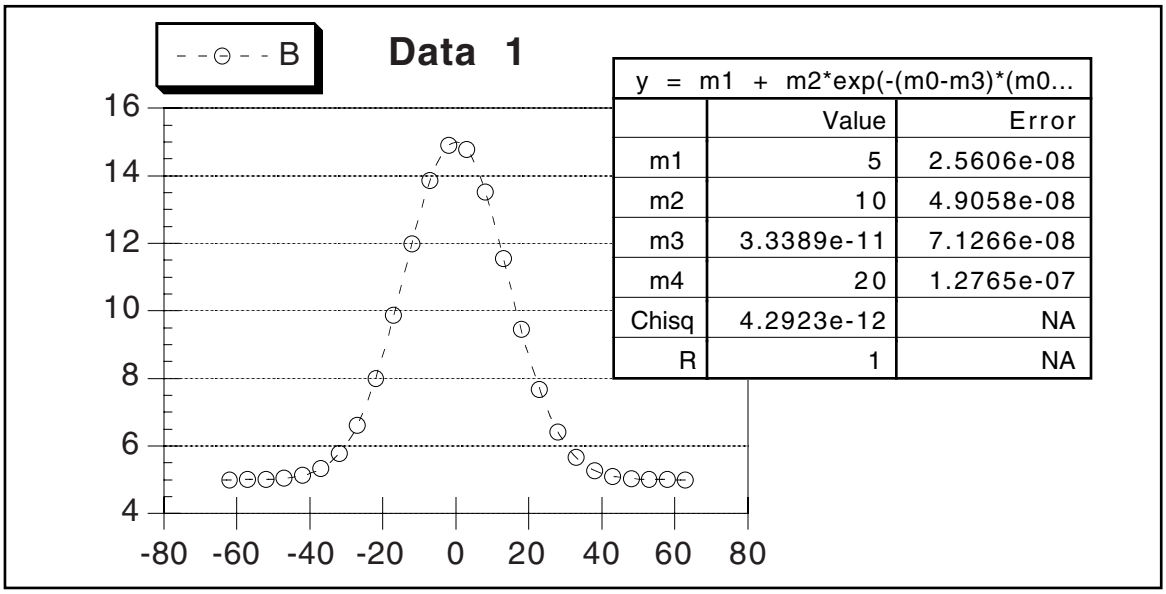

Figure 3-9 Sample plot with General curve fit applied

3.3.4 Weighting Data

The General curve fit provides an option to weight the data. When **Weight Data** is selected in the Curve Fit Definition dialog, the data is weighted during the curve fit. These weights are taken from a specified column in the data window. The weights should represent the individual error values of the fitted data.

Each weight is used internally as: 1/(weight^2). Specifying a weight less than 1.0 for a data point increases the internal weight of that point and can make the total error much larger. Weight values larger than 1.0 reduce the internal weights. When **Weight Data** is not selected, a weight value of 1.0 is used for all data points.

When the Weight Data option is selected and you choose a variable to fit, the dialog in Figure 3-10 appears. Use this dialog to select the column containing the weights for your data.

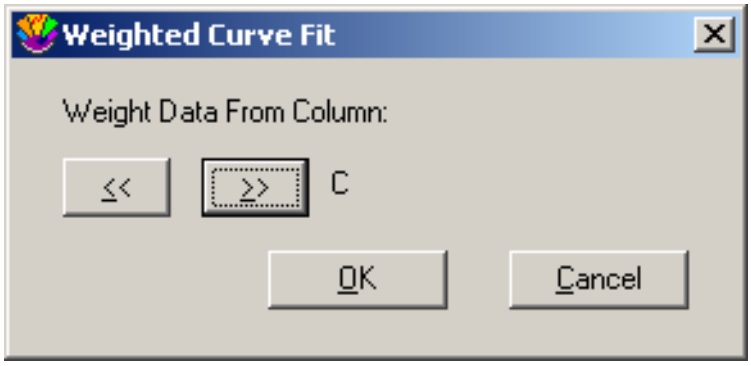

Figure 3-10 Selecting column of weights

3.3.5 Fitting Equations with Multiple Independent Variables

Through the use of the **table** function, KaleidaGraph can fit equations containing multiple independent variables. For example, to fit an equation like **y = a*x + b*x2 +c**, you would enter the following curve fit definition: **a*x + b*table(m0, x col, x2 col) + c**. You need to replace **x col** and **x2 col** with the appropriate column numbers from the data window (for example, table(m0, c0, c2)). The result of using the table function is that for each value of x, the corresponding value from the x2 column is evaluated as part of the curve fit.

3.3.6 Setting Limits for Curve Fit Parameters

Limits on curve fit parameters can be set in one of two ways. The first method is to use conditional testing on the parameter. The second method is to use the **limit** function from the default library.

Suppose that a General curve fit is being defined to fit a straight line to a set of data. The equation is of the form: **a+b*x**. In this example, you want to limit the value of b so that it is not a negative number.

In the Curve Fit Definition dialog, enter either of the following definitions:

```
a + (b=(b<0) ? 0 : b) *x; a=1; b=1     or     a + (b=limit(0, 1000, b))*x; a=1; b=1
```

In the first definition, a conditional test is performed to see if b is less than zero. If true, b is set to zero; if false, b is set equal to itself.

In the second definition, the limit function is used. The limit function requires that a lower and upper boundary be set for the parameter. In this case, zero and 1000 are used to bound the extremes of b.

Whenever a parameter is bound in a General curve fit definition, you must specify partial derivatives. Otherwise, a **Singular Coefficient Matrix error** may occur if the parameter being limited gets pegged at a bounding point for multiple iterations.

3.3.7 The General Curve Fit and the Macro Calculator

Calculations for the General curve fit are performed in the Macro Calculator. After performing a General curve fit, the memory registers in the Macro Calculator store information about the fit. The memory registers and their contents are listed below:

m0	R value
m1–m9	The values of the parameters.
m22	Chi Square value
m23	% error term
m24	Chi Square of the last iteration.
m25	Number of iterations completed.
m26	Number of parameters in the fit.

Note: Almost all memory registers, alpha registers, and program space are overwritten during the execution of a General curve fit.

Using Smooth Curve Fits

Chapter 4

This chapter provides information on the four smoothing curve fits available in KaleidaGraph and includes an example of applying a Cubic Spline curve fit to a plot.

4.1 KaleidaGraph's Smooth Curve Fits

4.1.1 Smooth

This function fits a smoothed curve to the data. KaleidaGraph starts by applying a Stineman function to the data. The output of this function then has a geometric weight applied to the current point and ±10% of the data range, to arrive at the smoothed curve.

The only data restriction associated with this curve fit is that the independent (X) variable must be in ascending order in the data window. There is no single expression that represents this curve; therefore, there are no parameters to view or copy.

4.1.2 Weighted

This function fits a curve to the data, using the locally weighted Least Squared error (Lowess) method. The result of this curve fit is to plot a best fit smooth curve through the center of the data. This is an extremely robust fitting technique. Unlike the standard Least Squared error method, this technique is nearly insensitive to outliers. However, this does not come for free. The Weighted curve fit is computationally complex and can take a very long time for a large data set.

The only data restriction associated with this curve fit is that the independent (X) variable must be in ascending order in the data window. There is no single expression that represents this curve; therefore, there are no parameters to view or copy.

4.1.3 Cubic Spline

Moving left to right along the curve in increasing X, every group of four consecutive data points defines a cubic polynomial equation. A series of these cubic polynomials connected together define a cubic spline curve. Using this curve fit is similar to using a French curve to connect all of the data points.

The only data restriction associated with this curve fit is that the independent (X) variable must be in ascending order in the data window. There is no single expression that represents this curve; therefore, there are no parameters to view or copy.

4.1.4 Interpolate

This function fits a curve that passes through the data points and matches the slopes at those points. The advantage of this curve fit is that it does not produce wild results near an abrupt change of slope, as can happen with the Cubic Spline curve fit.

The only data restriction associated with this curve fit is that the independent (X) variable must be in ascending order in the data window. There is no single expression that represents this curve; therefore, there are no parameters to view or copy.

4.2 Applying a Smoothing Fit

The following steps explain how to apply a smoothing fit, using the Cubic Spline curve fit as an example. The procedure is basically the same for applying the other smoothing fits.

To apply a Cubic Spline curve fit:

1. Open the plot window which will have the curve fit applied. Figure 4-1 shows a sample plot.

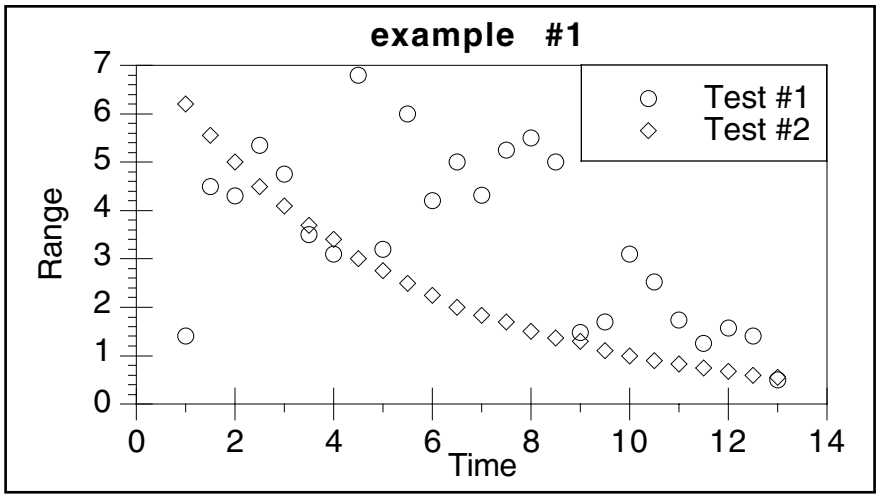

Figure 4-1 Sample plot

2. Choose **Curve Fit > Cubic Spline**. A Curve Fit Selections dialog similar to Figure 4-2 appears. All dependent variables are listed under **Column Names**.

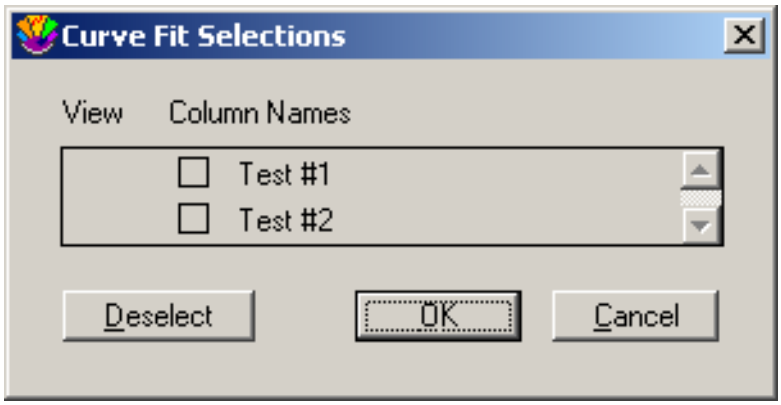

Figure 4-2 Curve Fit Selections dialog

3. Click the check box for each variable to be fit. A keyboard shortcut (**Ctrl+A** under Windows or ⌘**+A** on a Macintosh) is available to select all of the variables at once.

   Note: When applying a Weighted fit, a second dialog appears each time a variable is selected. Use this dialog to specify the smoothing factor.

4. Click **OK** to apply the curve fit.

   Note: If an error message appears saying the data needs to be sorted, you will need to use the **Ascending Sort** command from the **Data** menu. Once the independent variable is sorted, the curve fit can be applied.

After the curve fit is applied, you can increase the number of curve fit points or hide the original data to only display the curve fit. These are a few of the features covered in Chapter 6 of this guide. Figure 4-3 shows the sample plot after applying a Cubic Spline curve fit (represented by the solid line).

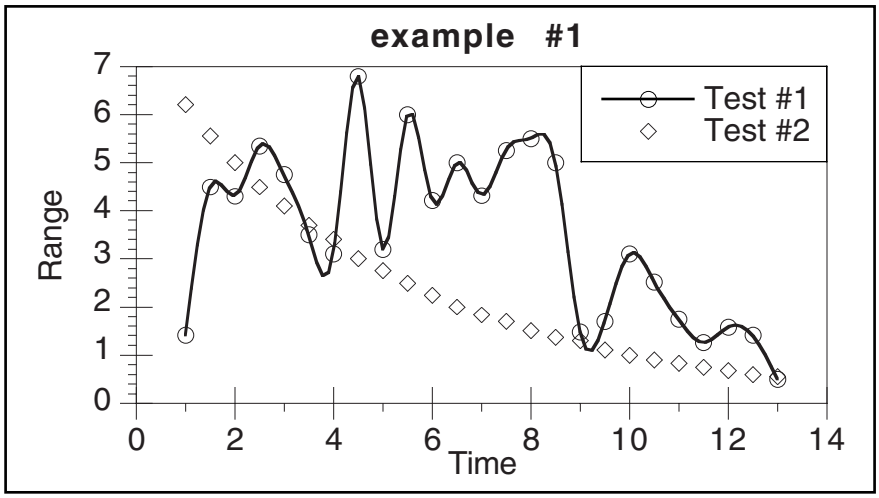

Figure 4-3 Sample plot with Cubic Spline curve fit applied

Working with Curve Fit Results

Chapter 5

This chapter explains how to:

- View the results of a curve fit.
- Interpret the values that are reported by KaleidaGraph.
- Export the curve fit results for further analysis.
- Obtain values from the curve fit line using Formula Entry.

5.1 Viewing Curve Fit Results

KaleidaGraph provides two methods to view the results of a curve fit. You can either display the equation on the plot or view the coefficients in a dialog.

5.1.1 Displaying the Curve Fit Equation

The curve fit equation can be displayed by turning on **Display Equation** in the **Plot** menu. The results from any General, Linear, Polynomial, Exponential, Logarithmic, or Power curve fits are displayed in the plot window. Not only is the resulting equation displayed, but if any updates occur to the curve fit, the equation updates automatically.

Depending on the type of curve fit, the equation is displayed in a table or as a text label. The General and Polynomial curve fits display equations in a table because the equations for these fits can be much longer than the others. The appearance of the equation can be edited by double-clicking it with the Selection Arrow.

The numeric format of the equation can be controlled using the **Equation Label Format** command (**Format** menu). Some of the options available include number format, number of significant digits, and trailing zeros.

5.1.2 Viewing Coefficients

The other method of displaying curve fit results is to view the curve fit's coefficients in a dialog.

To view the coefficients from the curve fit:

1. Reselect the curve fit from the **Curve Fit** menu. A Curve Fit Selections dialog similar to Figure 5-1 appears with a drop-down arrow under **View** for each variable that has a curve fit applied.

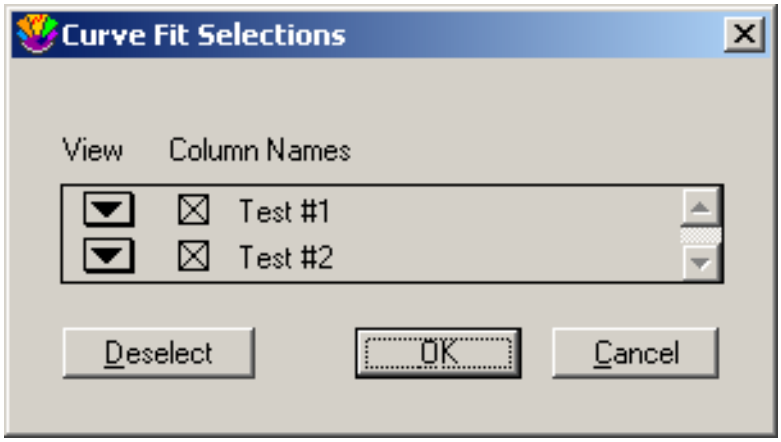

Figure 5-1 Curve Fit Selections dialog

2. Click one of the drop-down arrows and choose **View Results** from the pop-up menu that appears. A dialog similar to Figure 5-2 will be displayed containing the coefficients from the curve fit.

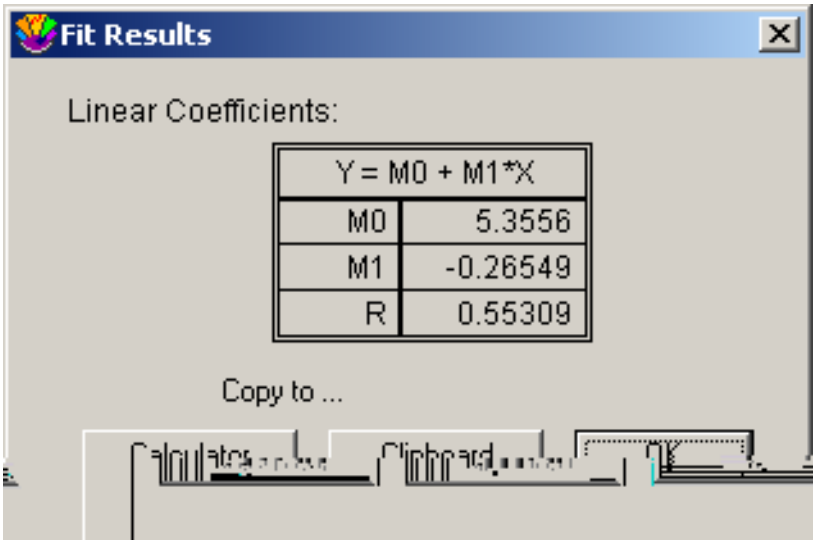

Figure 5-2 Viewing coefficients

3. To copy the coefficients to the Clipboard, click **Clipboard**. This enables you to paste the results into another window or program.
4. To copy the coefficients to the Calculator, click **Calculator**. This enables you to use the results in a Formula Entry function.
5. Click **OK** until you return to the plot window.

To calculate values from a curve fit:

1. Activate the data window that contains the fitted variables. Figure 5-5 shows a portion of the data used to create the sample plot.

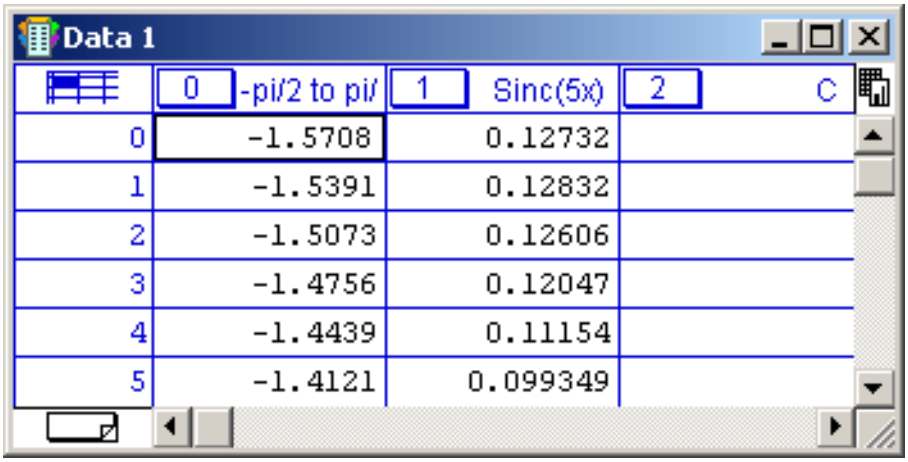

Figure 5-5 Data used to create sample plot

2. Choose **Windows > Formula Entry**.
3. Enter the formula into the window. Figure 5-6 shows the formula for this example. The formula should be of the form **z = fit(x,y)**, where:

   z is the destination column.
   x is either a single data value or a column containing X values.
   y is the column that had the curve fit applied.
   fit is replaced by the appropriate command from the **Curve Fits** menu of Formula Entry.

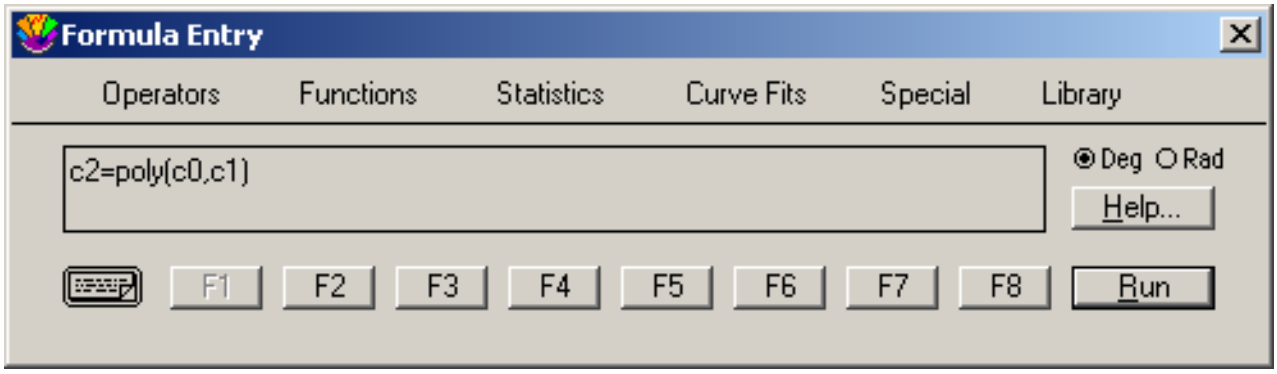

Figure 5-6 Curve fit function entered in Formula Entry

4. Click **Run** to execute the formula. The destination column is filled with the values of the curve fit at the specified X values. Figure 5-7 shows the resulting data window, with the curve fit values in the last column (column 2).

	0 -pi/2 to pi/	1 Sinc(5x)	2 C
0	-1.5708	0.12732	0.49307
1	-1.5391	0.12832	0.36896
2	-1.5073	0.12606	0.25821
3	-1.4756	0.12047	0.16017
4	-1.4439	0.11154	0.074163
5	-1.4121	0.099349	-0.00044013

Figure 5-7 Data window containing curve fit values

Note: This method uses the curve fit points originally calculated when the fit was applied. You may want to increase the number of calculated points to make the values from the fit more accurate. See Section 6.5 for instructions on increasing the number of curve fit points.

5.4.2 Using the Calculated Equation to Find Values

The most accurate method of getting values from a fit is to use the original equation and the parameters calculated by KaleidaGraph. This is not possible when a Smooth, Weighted, Cubic Spline, or Interpolate curve fit is applied to the data, because these curve fits do not result in an equation.

To calculate values using the curve fit's equation:

1. Copy the curve fit coefficients to the Calculator. Refer to Section 5.3.1 if you are unsure of how to do this. If you applied a General curve fit, you can skip this step because the parameters are automatically stored in the Calculator.
2. Activate the data window that contains the fitted variables. Figure 5-8 shows the original data with a column containing new X values (column 2).

	0 -pi/2 to pi/	1 Sinc(5x)	2 New X	3 D
0	-1.5708	0.12732	-1.5500	
1	-1.5391	0.12832	-1.4800	
2	-1.5073	0.12606	-1.4100	
3	-1.4756	0.12047	-1.3400	
4	-1.4439	0.11154	-1.2700	
5	-1.4121	0.099349	-1.2000	

Figure 5-8 Data window containing new X values

3. Choose **Windows > Formula Entry**.
4. Enter your formula into the window. Figure 5-9 shows the formula used to obtain values from a curve fit at designated points, where:
   c3 is the destination column for the curve fit values.
   c2 is the column containing the new X values.
   m0–m5 are the curve fit coefficients previously copied to the Calculator.

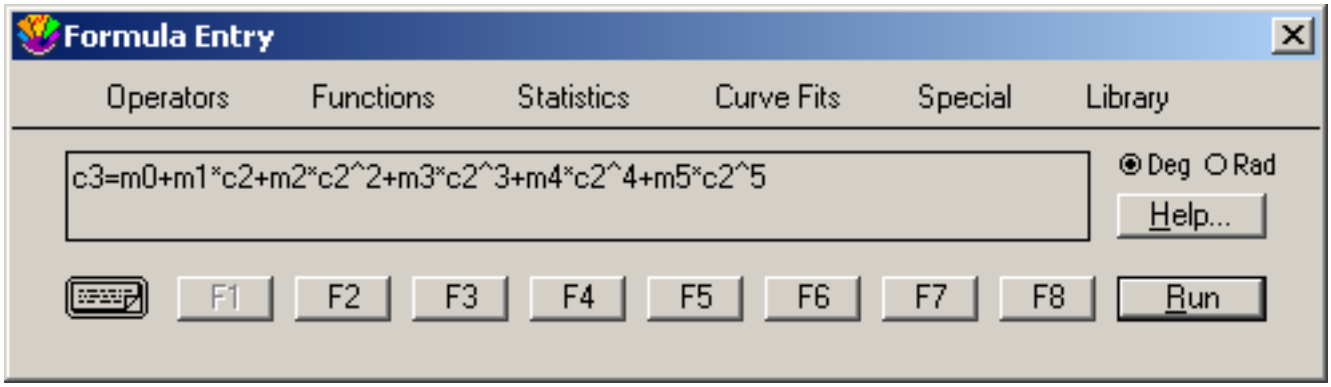

Figure 5-9 Using the curve fit equation to calculate values

5. Click **Run** to execute the formula. The destination column is filled with the values of the curve fit at the specified X values. Figure 5-10 shows the resulting data window, with the curve fit values in the last column (column 3).

	0 -pi/2 to pi/	1 Sinc(5x)	2 New X	3 D
0	-1.5708	0.12732	-1.5500	0.41019
1	-1.5391	0.12832	-1.4800	0.17304
2	-1.5073	0.12606	-1.4100	-0.0050533
3	-1.4756	0.12047	-1.3400	-0.13091
4	-1.4439	0.11154	-1.2700	-0.21103
5	-1.4121	0.099349	-1.2000	-0.25158

Figure 5-10 Data window containing curve fit values

Note: This method can similarly be used to calculate the X value when the Y value on the fit is known. You need to rearrange the formula so that it solves for X instead of Y.

Other Curve Fit Features

Chapter 6

This chapter explains how to:

- Change the appearance of the curve fit.
- Display just the curve fit line on the plot.
- Extrapolate a curve fit to the axis limits.
- Force a Linear fit through the origin.
- Increase the number of curve fit points.
- Remove a curve fit.

6.1 Changing Appearance of Curve Fit Lines

To change the line style, width, or color of curve fit lines:

1. With the plot window active, choose **Plot > Plot Style**.
2. Select the variable to be edited.
3. Click **Curve Fit** to make changes to the curve fit line.
4. To change the line style, select a different option from the **Style** column. Choose **None** from this list to hide the line. The current style is preceded by a check mark.
5. To change the line width, select a different option from the **Width** column. The current width is preceded by a check mark.
6. To change the color, select a different color from the palette. The current color has a white square around it.
7. Click **OK** to return to the plot.

6.2 Displaying Only the Curve Fit

There may be times when you are only interested in displaying the curve fit on the plot without the original data points. This can be accomplished using the Plot Style dialog, provided the plot is not a Scatter plot.

To display only the curve fit:

1. With the plot window active, choose **Plot > Plot Style**. The Plot Style dialog appears.
2. Select the variable to be hidden.
3. Select **None** from the **Show Markers** pop-up menu and **None** for the Line Style. This hides the markers and line used to represent the original data.
4. Click **OK** to return to the plot. The variable is hidden and only the curve fit is displayed.

6.3 Extrapolating to the Axis Limits

Curve fits are normally displayed between the minimum and maximum data values plotted on the independent axis. However, you can choose to extrapolate the curve fits to the axis limits. The extrapolated portion of the fit is based on the calculated equation.

Note: It is not possible to extrapolate the Smoothing fits (Smooth, Weighted, Cubic Spline, and Interpolate) because they cannot be represented by a single equation.

To extrapolate a curve fit:

1. Choose **Format > Curve Fit Options**. The dialog in Figure 6-1 appears.

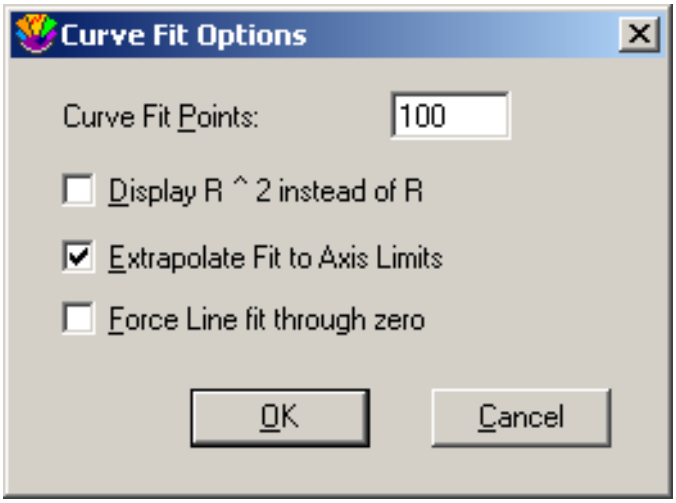

Figure 6-1 Curve Fit Options dialog

2. Select the **Extrapolate Fit to Axis Limits** check box.
3. Click **OK** to return to the plot. After recalculating the curve fits, the plot is redrawn to extend the curve fits to the axis limits.

6.4 Forcing a Linear Fit Through the Origin

By default, the slope and intercept are calculated when applying a Linear curve fit. KaleidaGraph provides an option that forces the curve fit to pass through the origin (0,0), so that only the slope of the line is calculated.

To force a Linear curve fit through the origin:

1. Choose **Format > Curve Fit Options**.
2. Select the **Force Line fit through zero** check box.
3. Click **OK** to return to the plot. Any Linear curve fits are recalculated with a Y-intercept of zero.

6.5 Increasing the Number of Curve Fit Points

Any time a curve fit is applied (except for the Weighted fit), KaleidaGraph calculates a predetermined number of points along the fit. These points are used to draw the curve fit and calculate values from the fit. You may find it useful to increase the number of curve fit points when using Formula Entry to place values from the fit into the data window. This increases the accuracy of these values.

To increase the number of curve fit points:

1. Choose **Format > Curve Fit Options**.
2. Enter a different value in the **Curve Fit Points** field. A good starting point is to enter the number of points that were plotted. You may want to make this value even higher if there are a number of peaks and valleys in the data.
3. Click **OK** to return to the plot window and recalculate the fits.

6.6 Removing a Curve Fit

Curve fits can be removed from a plot in the same way that they are added. After applying a curve fit, a check mark appears next to that type of fit in the **Curve Fit** menu to indicate that a curve fit is applied.

To remove a curve fit from the plot:

1. From the **Curve Fit** menu, choose the type of curve fit to be removed. A dialog similar to Figure 6-2 is displayed containing the list of variables. The check box of each fitted variable is selected.

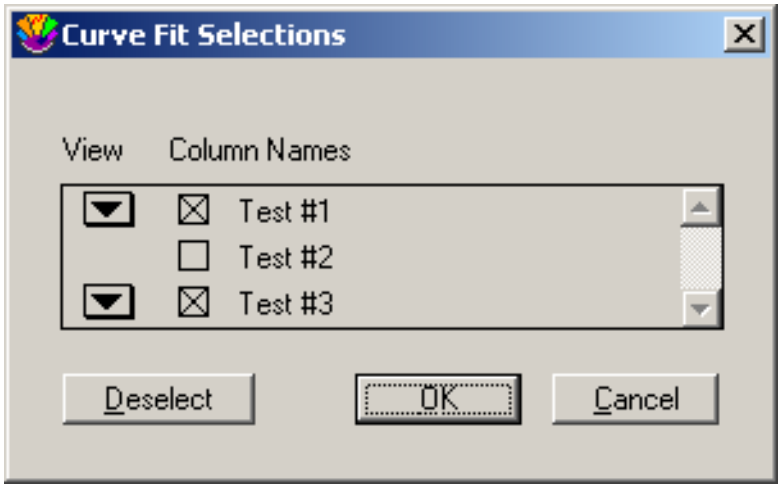

Figure 6-2 Curve Fit Selections dialog

2. Clear any check boxes for the fits to be removed. Clicking **Deselect** clears all of the check boxes at once.
3. Click **OK** to return to the plot and remove the curve fits and any associated equations.

Troubleshooting Curve Fit Problems

Appendix A

Singular Coefficient Matrix error message
KaleidaGraph could not converge on a solution or was getting a divide by zero error in the General curve fit. Verify that none of the initial guesses are set to 0. Try changing the initial guesses to steer KaleidaGraph away from whatever caused the error. You can also try to specify the partial derivatives to point KaleidaGraph in the right direction after each iteration.

The data must be sorted first error message.
This error results when you attempt to apply a Smooth, Weighted, Cubic Spline, or Interpolate curve fit to data which does not have the independent variable sorted in ascending order. Once the independent variable is sorted using the **Ascending Sort** command (**Functions** menu), the curve fit can be applied.

Syntax Errors
These result when illegal characters or undefined functions are used in a curve fit definition. Some common mistakes include using the letter o instead of a zero, having a different number of left and right parentheses, and attempting to call a library function that is not defined in the current library.

Syntax error in the Macro Library error message.
This error results when the library contains an undefined function. These errors commonly result when opening a saved curve fit definition in the library instead of opening it in the Curve Fit Definition dialog.

To replace the current contents of the Library with the default Macro Library:

1. Select the **Library** command from either the **Macros** menu or the **Curve Fit** menu.
2. Choose **File > Open**.
3. Locate and open the **Library** file within the **Library** folder and open it.
4. Choose **File > Exit**.
5. After doing this, make sure you save the Macros when quitting KaleidaGraph in order for the Library to be saved as part of the KG Macros file.

Tried to limit the parameter values, but the resulting parameters were outside of the specified limits.
It is possible to get values outside of the limits. During each iteration, KaleidaGraph tries to improve upon the parameter values to get the best fit. These new values are not passed through the function to limit their value. The number you are seeing is KaleidaGraph's last best guess at what the value should be. Right now, the only way to avoid this is to replace the unknown with a constant.

Not getting the correct results when typing the results of a curve fit into a formula.
By default, the results of a curve fit are displayed with five significant digits. You can obtain more accuracy by choosing **Format > Equation Label Format** and increasing the number of digits or decimals. This will make the results of your formula more accurate.

Another solution is to copy the results of the curve fit to the Calculator. These values are always stored as double precision numbers. See Section 5.3.1 for more information on copying the results to the Calculator.

Linear Fits on Plots with Log or Semi-Log Scales
When applying a Linear curve fit to data displayed on a log-log or semi-log scale, the curve fit may not appear to be a straight line. This is because the divisions along logarithmic axes are not equally spaced. However, it is possible to get the appearance of a straight line on plots with either log-log or semi-log scales.

You can get the appearance of a straight line on a plot with a log-log scale (both the X and Y axes are logarithmic) by applying a Power curve fit to the data. The resulting curve fit will look like a straight line.

Getting the appearance of a straight line on a plot with a semi-log scale (either the X or Y axis is logarithmic) depends on which axis is logarithmic:

- If the X axis is logarithmic (Y axis is linear), applying a Logarithmic curve fit will result in a straight line.
- If the Y axis is logarithmic (X axis is linear), applying an Exponential curve fit will result in a straight line.

Reference Information

Appendix B

This chapter provides information on the methods and equations used when performing regression analysis in KaleidaGraph.
